- L.O.2.1 Depict the following concepts: (a) array list and linked list, including single link and double links, and multiple links; (b) stack; and (c) queue and circular queue.
- L.O.2.2 Describe storage structures by using pseudocode for: (a) array list and linked list, including single link and double links, and multiple links; (b) stack; and (c) queue and circular queue.
- L.O.2.3 List necessary methods supplied for list, stack, and queue, and describe them using pseudocode.
- L.O.2.4 Implement list, stack, and queue using C/C++.

Applications of Queue

• L.O.2.5 - Use list, stack, and queue for problems in real-life, and choose an appropriate implementation type (array vs. link).

- L.O.2.6 Analyze the complexity and develop experiment (program) to evaluate the efficiency of methods supplied for list, stack, and queue.
- L.O.8.4 Develop recursive implementations for methods supplied for the following structures: list, tree, heap, searching, and graphs.
- L.O.1.2 Analyze algorithms and use Big-O notation to characterize the computational complexity of algorithms composed by using the following control structures: sequence, branching, and iteration (not recursion).

Linear List Concepts

General list:

- No restrictions on which operation can be used on the list.
- No restrictions on where data can be inserted/deleted.

Restricted list:

- Only some operations can be used on the list.
- Data can be inserted/deleted only at the ends of the list.

Stack

Definition

A stack of elements of type T is a finite sequence of elements of T, in which all insertions and deletions are restricted to one end, called the top.

Stack is a Last In - First Out (LIFO) data structure. LIFO: The last item put on the stack is the first item that can be taken off.

Basic operations of Stacks

Basic operations:

- Construct a stack, leaving it empty.
- Push an element: put a new element on to the top of the stack.
- Pop an element: remove the top element from the top of the stack.
- Top an element: retrieve the top element.

Extended operations:

- Determine whether the stack is empty or not.
- Determine whether the stack is full or not.
- Find the size of the stack.
- Clear the stack to make it empty.

Push data into a Linked Stack

- 1 Allocate memory for the new node and set up data.
- 2 Update pointers:
 - Point the new node to the top node (before adding the new node).
 - Point top to the new node.
- 3 Update count

Implementation of array-based stack is very simple. It uses top variable to point to the topmost stack's element in the array.

- 1 Initialy top = -1;
- 2 push operation increases top by one and writes pushed element to storage[top];
- 3 pop operation checks that top is not equal to -1 and decreases top variable by 1;
- 4 getTop operation checks that top is not equal to -1
 and returns storage[top];
- **5** isEmpty returns boolean if top == −1.

Definition

A queue of elements of type T is a finite sequence of elements of T, in which data can only be inserted at one end called the rear, and deleted from the other end called the front.

Queue is a First In - First Out (FIFO) data structure. FIFO: The first item stored in the queue is the first item that can be taken out.

Algorithm dequeue(ref queue <metadata>, ref dataOut <dataType>)

Deletes one item at the front of the queue and returns its data to caller

Pre: queue is a metadata structure of a valid queue dataOut is to receive dequeued data

Post: front data have been returned to caller **Return** true if successful, false if memory overflow

if queue empty then return false
